Campus Network Design Workshop

Layer 2 Engineering – Spanning Tree and VLANs

This document is a result of work by the Network Startup Resource Center (NSRC at http://www.nsrc.org). This document may be freely copied, modified, and otherwise re-used on the condition that any re-use acknowledge the NSRC as the original source.

- When there is more than one path between two switches
- What are the potential problems?

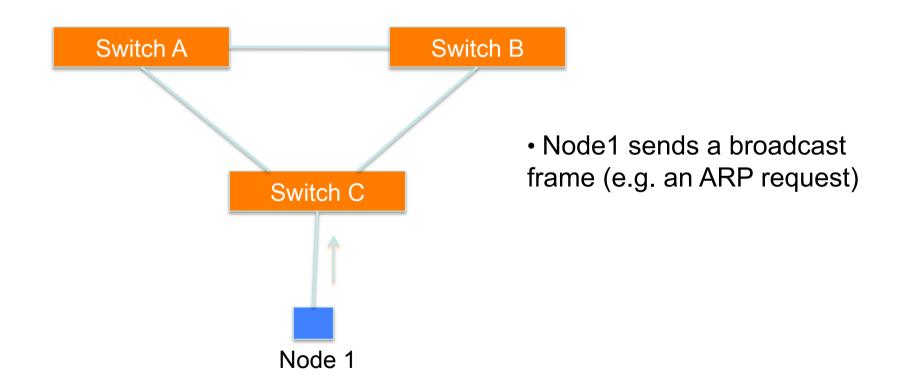

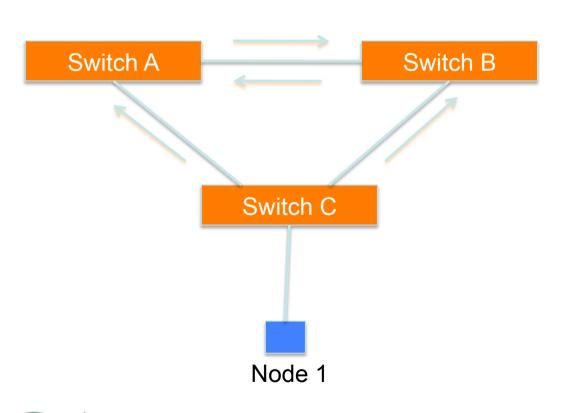

- If there is more than one path between two switches:
 - Forwarding tables become unstable
 - Source MAC addresses are repeatedly seen coming from different ports
 - Switches will broadcast each other's broadcasts
 - All available bandwidth is utilized
 - Switch processors cannot handle the load

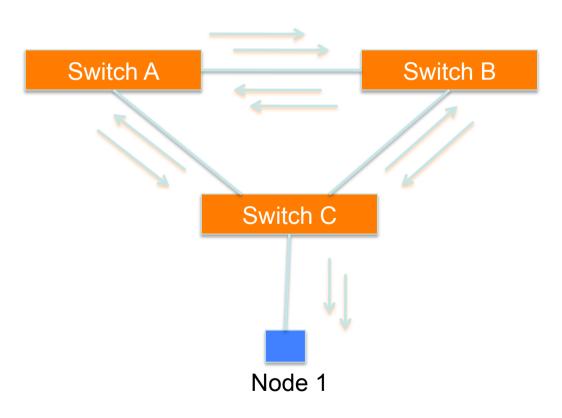

UNIVERSITY OF OREGON

 Switches A, B and C broadcast node 1's frame out every port

- But they receive each other's broadcasts, which they need to forward again out every port!
- The broadcasts are amplified, creating a broadcast storm

Good Switching Loops

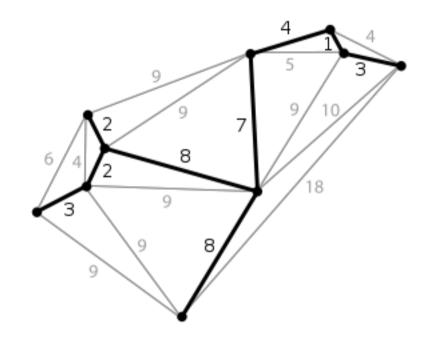

- But you can take advantage of loops!
 - Redundant paths improve resilience when:
 - A switch fails
 - Wiring breaks
- How to achieve redundancy without creating dangerous traffic loops?

What is a Spanning Tree?

- "Given a connected, undirected graph, a spanning tree of that graph is a subgraph which is a tree and connects all the vertices together".
- A single graph can have many different spanning trees.

Spanning Tree Protocol

 The purpose of the protocol is to have bridges dynamically discover a subset of the topology that is loop-free (a tree) and yet has just enough connectivity so that where physically possible, there is a path between every switch

Spanning Tree Protocol

- Several flavors:
 - Traditional Spanning Tree (802.1d)
 - Rapid Spanning Tree or RSTP (802.1w)
 - Multiple Spanning Tree or MSTP (802.1s)

Traditional Spanning Tree (802.1d)

- Switches exchange messages that allow them to compute the Spanning Tree
 - These messages are called BPDUs (Bridge Protocol Data Units)
 - Two types of BPDUs:
 - Configuration
 - Topology Change Notification (TCN)

Traditional Spanning Tree (802.1d)

First Step:

- Decide on a point of reference: the Root Bridge
- The election process is based on the Bridge ID, which is composed of:
 - The Bridge Priority: A two-byte value that is configurable
 - The MAC address: A unique, hardcoded address that cannot be changed.

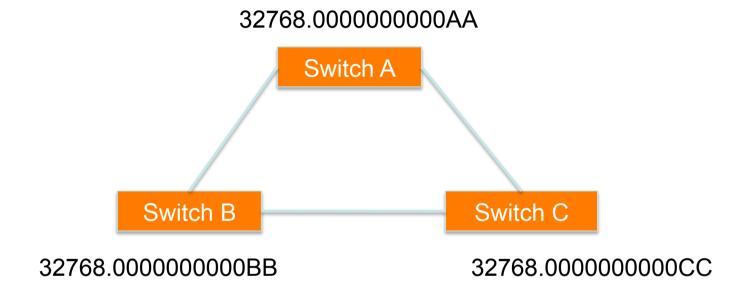

Root Bridge Selection (802.1d)

- Each switch starts by sending out BPDUs with a Root Bridge ID equal to its own Bridge ID
 - I am the root!
- Received BPDUs are analyzed to see if a <u>lower</u>
 Root Bridge ID is being announced
 - If so, each switch replaces the value of the advertised Root Bridge ID with this new lower ID
- Eventually, they all agree on who the Root Bridge is

Root Bridge Selection (802.1d)

- All switches have the same priority.
- Who is the elected root bridge?

- Now each switch needs to figure out where it is in relation to the Root Bridge
 - Each switch needs to determine its Root Port
 - The key is to find the port with the <u>lowest</u> Root Path
 Cost
 - The cumulative cost of all the links leading to the Root Bridge

- Each link on a switch has a Path Cost
 - Inversely proportional to the link speed
 - e.g. The faster the link, the lower the cost

Link Speed	STP Cost
10 Mbps	100
100 Mbps	19
1 Gbps	4
10 Gbps	2

- Root Path Cost is the accumulation of a link's Path Cost and the Path Costs learned from neighboring Switches.
 - It answers the question: How much does it cost to reach the Root Bridge through this port?

- Root Bridge sends out BPDUs with a Root Path Cost value of 0
- Neighbor receives BPDU and adds port's Path Cost to Root Path Cost received
- 3. Neighbor sends out BPDUs with new cumulative value as Root Path Cost
- 4. Other neighbors down the line keep adding in the same fashion

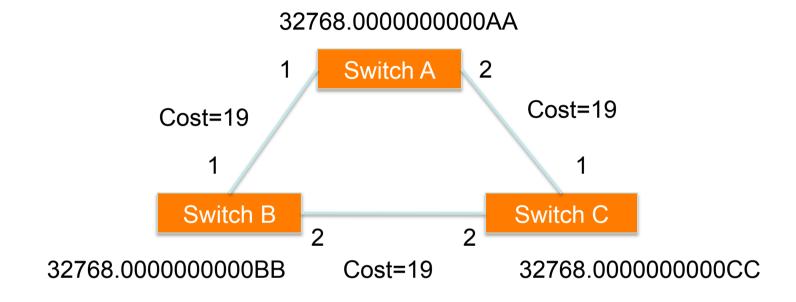

- On each switch, the port where the lowest Root Path Cost was received becomes the *Root Port*
 - This is the port with the best path to the Root Bridge

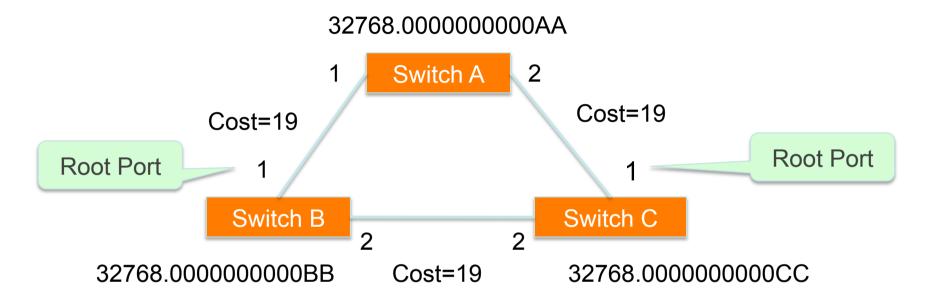

- What is the Path Cost on each Port?
- What is the Root Port on each switch?

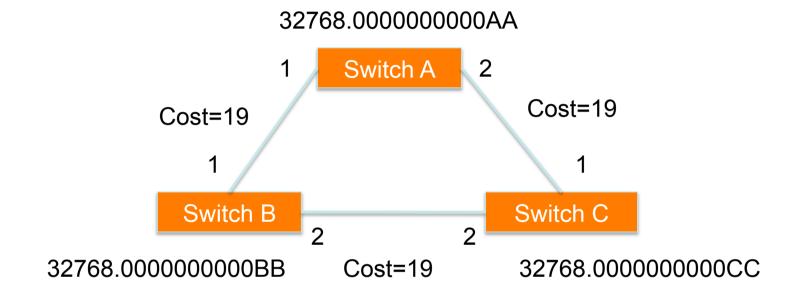

- OK, we now have selected root ports but we haven't solved the loop problem yet, have we
 - The links are still active!
- Each network segment needs to have only one switch forwarding traffic to and from that segment
- Switches then need to identify one *Designated Port* per link
 - The one with the lowest cumulative Root Path Cost to the Root Bridge

 Which port should be the Designated Port on each segment?

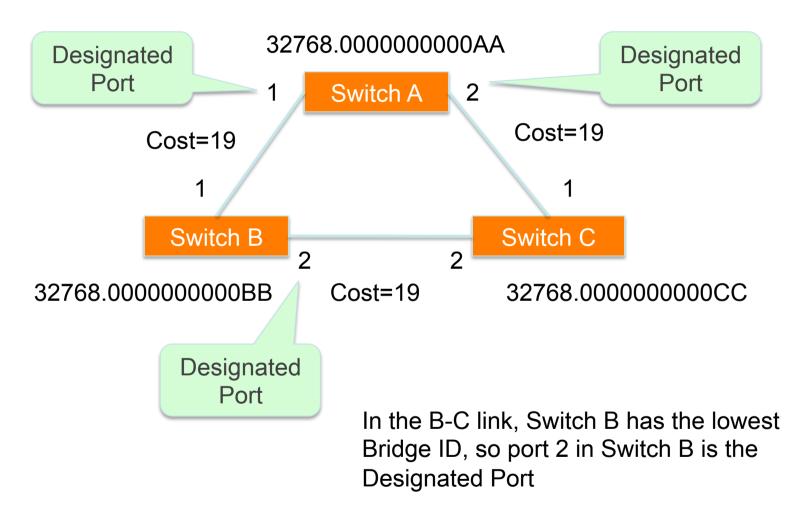

- Two or more ports in a segment having identical Root Path Costs is possible, which results in a tie condition
- All STP decisions are based on the following sequence of conditions:
 - Lowest Root Bridge ID
 - Lowest Root Path Cost to Root Bridge
 - Lowest Sender Bridge ID
 - Lowest Sender Port ID

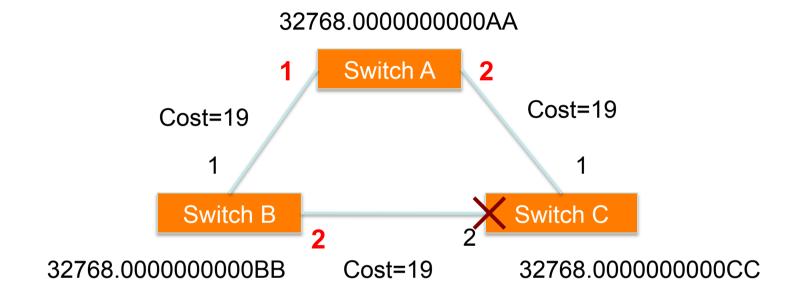

Blocking a port

- Any port that is not elected as either a Root Port, nor a Designated Port is put into the **Blocking** State.
- This step effectively breaks the loop and completes the Spanning Tree.

Designated Ports on each segment (802.1d)

 Port 2 in Switch C is then put into the Blocking State because it is neither a Root Port nor a Designated Port

Spanning Tree Protocol States

- Disabled
 - Port is shut down
- Blocking
 - Not forwarding frames
 - Receiving BPDUs
- Listening
 - Not forwarding frames
 - Sending and receiving BPDUs

Spanning Tree Protocol States

- Learning
 - Not forwarding frames
 - Sending and receiving BPDUs
 - Learning new MAC addresses
- Forwarding
 - Forwarding frames
 - Sending and receiving BPDUs
 - Learning new MAC addresses

STP Topology Changes

- Switches will recalculate if:
 - A new switch is introduced
 - It could be the new Root Bridge!
 - A switch fails
 - A link fails

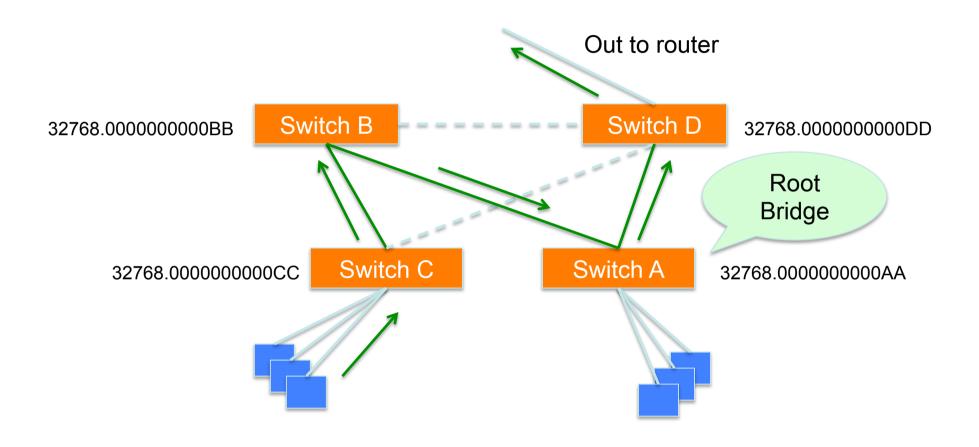

Root Bridge Placement

- Using default STP parameters might result in an undesired situation
 - Traffic will flow in non-optimal ways
 - An unstable or slow switch might become the root
- You need to plan your assignment of bridge priorities carefully

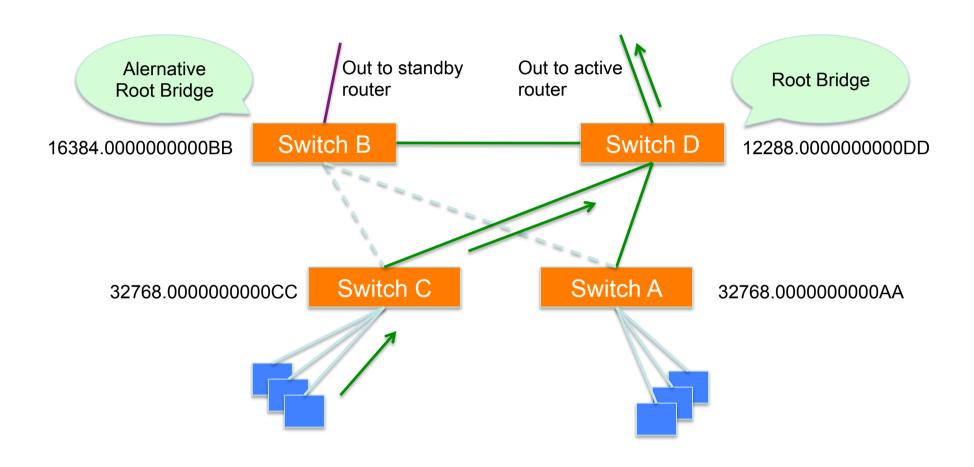

Bad Root Bridge Placement

Good Root Bridge Placement

Protecting the STP Topology

- Some vendors have included features that protect the STP topology:
 - Root Guard
 - BPDU Guard
 - Loop Guard
 - UDLD
 - Etc.

STP Design Guidelines

- Enable spanning tree even if you don't have redundant paths
- Always plan and set bridge priorities
 - Make the root choice deterministic
 - Include an alternative root bridge
- If possible, do not accept BPDUs on end user ports
 - Apply BPDU Guard or similar where available

802.1d Convergence Speeds

- Moving from the Blocking state to the Forwarding State takes at least 2 x Forward Delay time units (~ 30 secs.)
 - This can be annoying when connecting end user stations
- Some vendors have added enhancements such as PortFast, which will reduce this time to a minimum for edge ports
 - Never use PortFast or similar in switch-to-switch links
- Topology changes typically take 30 seconds too
 - This can be unacceptable in a production network

- Convergence is much faster
 - Communication between switches is more interactive
- Edge ports don't participate
 - Edge ports transition to forwarding state immediately
 - If BPDUs are received on an edge port, it becomes a non-edge port to prevent loops

- Defines these port roles:
 - Root Port (same as with 802.1d)
 - Alternate Port
 - A port with an alternate path to the root
 - Designated Port (same as with 802.1d)
 - Backup Port
 - A backup/redundant path to a segment where another bridge port already connects.

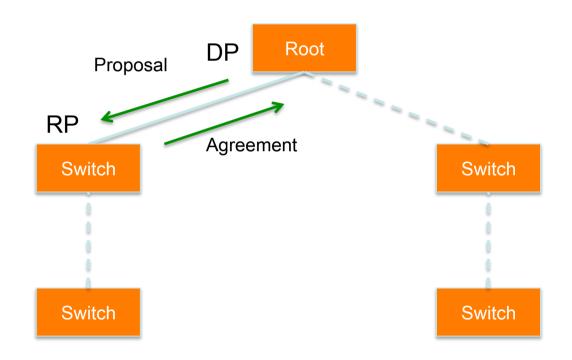

- Synchronization process uses a handshake method
 - After a root is elected, the topology is built in cascade, where each switch proposes to be the designated bridge for each point-to-point link
 - While this happens, all the downstream switch links are blocking

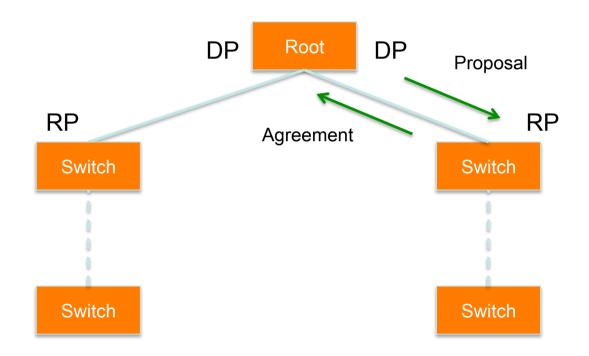

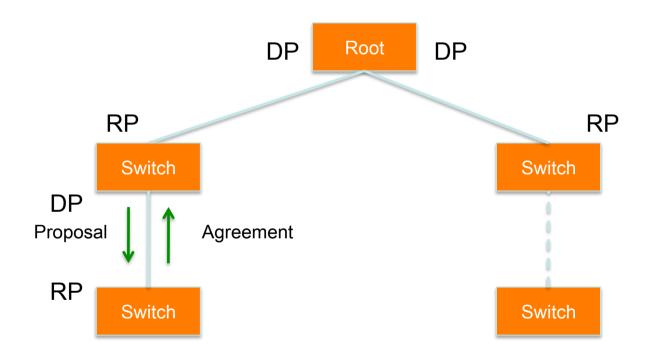

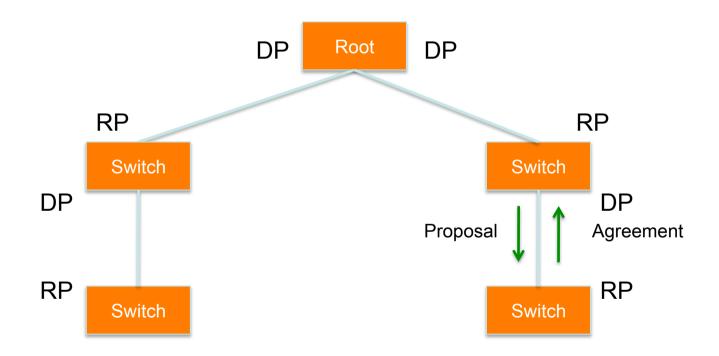

- Prefer RSTP over STP if you want faster convergence
- Always define which ports are edge ports

Questions?

Virtual LANs (VLANs)

- Allow us to split switches into separate (virtual) switches
- Only members of a VLAN can see that VLAN's traffic
 - Inter-vlan traffic must go through a router
- Allow us to reuse router interfaces to carry traffic for separate subnets
 - E.g. sub-interfaces in Cisco routers

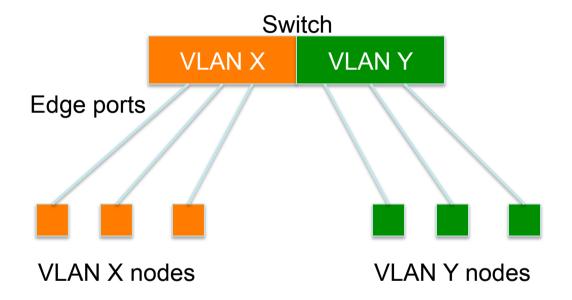

Local VLANs

- 2 VLANs or more within a single switch
- *Edge ports*, where end nodes are connected, are configured as members of a VLAN
- The switch behaves as several virtual switches, sending traffic only within VLAN members

Local VLANs

VLANs across switches

- Two switches can exchange traffic from one or more VLANs
- Inter-switch links are configured as trunks, carrying frames from all or a subset of a switch's VLANs
- Each frame carries a tag that identifies which VLAN it belongs to

802.1Q

- The IEEE standard that defines how ethernet frames should be tagged when moving across switch trunks
- This means that switches from *different vendors* are able to exchange VLAN traffic.

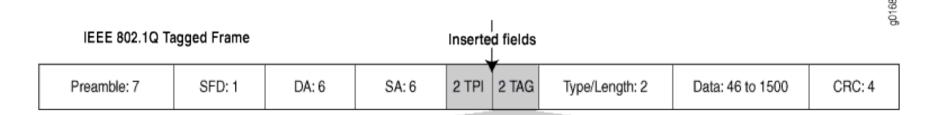

802.1Q tagged frame

Normal Ethernet frame

SFD: 1 DA: 6 SA: 6 Type/Length: 2 Data: 46 to 1500 CRC: 4	SA: 6	DA: 6	SFD: 1	Preamble: 7
---	-------	-------	--------	-------------

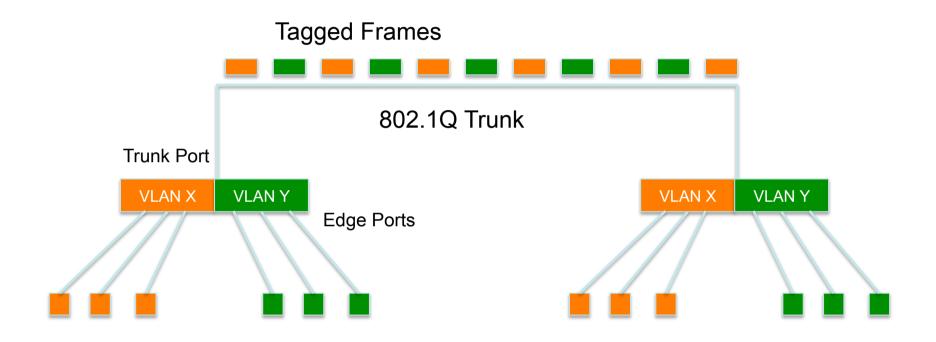

User Priority	CFI	12 bits of VLAN ID to identify 4,096 possible VLANs
3 bits	1 bit	12 bits

VLANs across switches

This is called "VLAN Trunking"

Tagged vs. Untagged

- Edge ports are not tagged, they are just "members" of a VLAN
- You only need to tag frames in switch-to-switch links (trunks), when transporting multiple VLANs
- A trunk can transport both tagged and untagged VLANs
 - As long as the two switches agree on how to handle those

VLANs increase complexity

- You can no longer "just replace" a switch
 - Now you have VLAN configuration to maintain
 - Field technicians need more skills
- You have to make sure that all the switch-toswitch trunks are carrying all the necessary VLANs
 - Need to keep in mind when adding/removing VLANs

Good reasons to use VLANs

- You want to segment your network into multiple subnets, but can't buy enough switches
 - Hide sensitive infrastructure like IP phones, building controls, etc.
- Separate control traffic from user traffic
 - Restrict who can access your switch management address

Bad reasons to use VLANs

- Because you can, and you feel cool ☺
- Because they will completely secure your hosts (or so you think)
- Because they allow you to extend the same IP network over multiple separate buildings
 - This is actually very common, but a bad idea

Do not build "VLAN spaghetti"

- Extending a VLAN to multiple buildings across trunk ports
- Bad idea because:
 - Broadcast traffic is carried across all trunks from one end of the network to another
 - Broadcast storm can spread across the extent of the VLAN, and affect all VLANS!
 - Maintenance and troubleshooting nightmare

Link Aggregation

- Also known as port bundling, link bundling
- You can use multiple links in parallel as a single, logical link
 - For increased capacity
 - For redundancy (fault tolerance)
- LACP (Link Aggregation Control Protocol) is a standardized method of negotiating these bundled links between switches

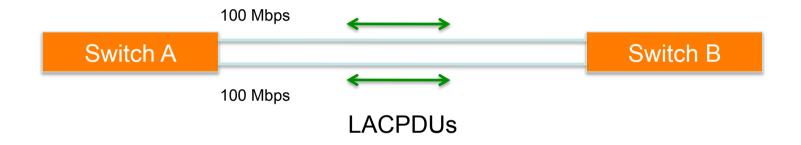

LACP Operation

- Two switches connected via multiple links will send LACPDU packets, identifying themselves and the port capabilities
- They will then automatically build the logical aggregated links, and then pass traffic.
- Switch ports can be configured as active or passive

LACP Operation

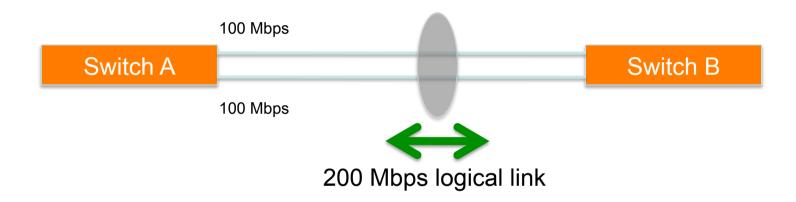

- Switches A and B are connected to each other using two sets of Fast Ethernet ports
- LACP is enabled and the ports are turned on
- Switches start sending LACPDUs, then negotiate how to set up the aggregation

LACP Operation

- The result is an aggregated 200 Mbps logical link
- The link is also fault tolerant: If one of the member links fail, LACP will automatically take that link off the bundle, and keep sending traffic over the remaining link

Distributing Traffic in Bundled Links

- Bundled links distribute frames using a hashing algorithm, based on:
 - Source and/or Destination MAC address
 - Source and/or Destination IP address
 - Source and/or Destination Port numbers
- This can lead to unbalanced use of the links, depending on the nature of the traffic
- Always choose the load-balancing method that provides the most distribution

Questions?

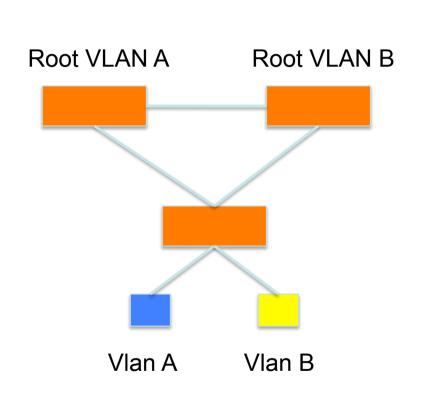

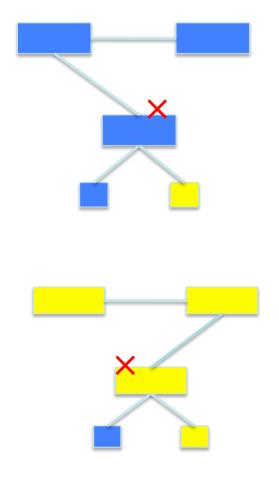

- Allows separate spanning trees per VLAN group
 - Different topologies allow for load balancing between links
 - Each group of VLANs are assigned to an "instance" of MST
- Compatible with STP and RSTP

MST Region

- Switches are members of a region if they have the same set of attributes:
 - MST configuration name
 - MST configuration revision
 - Instance-to-VLAN mapping
- A digest of these attributes is sent inside the BPDUs for fast comparison by the switches
- One region is usually sufficient

- CST = Common Spanning Tree
 - In order to interoperate with other versions of Spanning Tree, MST needs a common tree that contains all the other islands, including other MST regions

- IST = Internal Spanning Tree
 - Internal to the Region, that is
 - Presents the entire region as a single virtual bridge to the CST outside

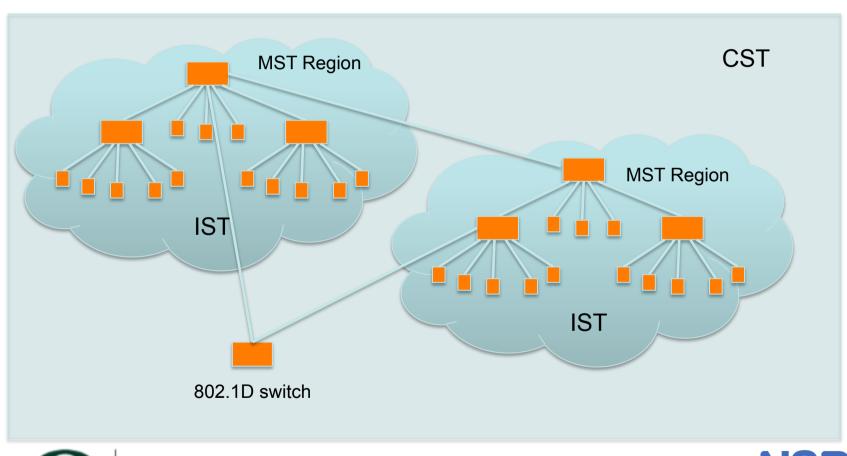

MST Instances

- Groups of VLANs are mapped to particular Spanning Tree instances
- These instances will represent the alternative topologies, or forwarding paths
- You specify a root and alternate root for each instance

Design Guidelines

- Determine relevant forwarding paths, and distribute your VLANs equally into instances matching these topologies
- Assign different root and alternate root switches to each instance
- Make sure all switches match region attributes
- Do not assign VLANs to instance 0, as this is used by the IST

- Minimum features:
 - Standards compliance
 - Encrypted management (SSH/HTTPS)
 - VLAN trunking
 - Spanning Tree (RSTP at least)
 - SNMP
 - At least v2 (v3 has better security)
 - Traps

- Other recommended features:
 - DHCP Snooping
 - Prevent end-users from running a rogue DHCP server
 - Happens a lot with little wireless routers (Netgear, Linksys, etc)
 plugged in backwards
 - Uplink ports towards the legitimate DHCP server are defined as "trusted". If DHCPOFFERs are seen coming from any untrusted port, they are dropped.

- Other recommended features:
 - Dynamic ARP inspection
 - A malicious host can perform a man-in-the-middle attack by sending gratuitous ARP responses, or responding to requests with bogus information
 - Switches can look inside ARP packets and discard gratuitous and invalid ARP packets.

- Other recommended features:
 - IGMP Snooping:
 - Switches normally flood multicast frames out every port
 - Snooping on IGMP traffic, the switch can learn which stations are members of a multicast group, thus forwarding multicast frames only out necessary ports
 - Very important when users run Norton Ghost, for example.

Network Management

- Enable SNMP traps and/or syslog
 - Collect and process in centralized log server
 - Spanning Tree Changes
 - Duplex mismatches
 - Wiring problems
- Monitor configurations
 - Use RANCID to report any changes in the switch configuration

Network Management

- Collect forwarding tables with SNMP
 - Allows you to find a MAC address in your network quickly
 - You can use simple text files + grep, or a web tool with DB backend
- Enable LLDP (or CDP or similar)
 - Shows how switches are connected to each other and to other network devices

Documentation

- Document where your switches are located
 - Name switch after building name
 - E.g. building1-sw1
 - Keep files with physical location
 - Floor, closet number, etc.
- Document your edge port connections
 - Room number, jack number, server name
